## Abstract

Due to the need of a large group of people, including the elderly, autistic patients, the disabled, and people with chronic diseases for daily care, we designed this application that contributes to solving this problem by allowing the user to book home care appointments or an assistant to help with achieving daily tasks by a nurse or specialist for a period of time in hours or days or weeks.

In this report, we will show how we implemented the solution by using NetBeans and java programming language and how we applied some design patterns in the application. In fact, the design patterns help promote easier program changes and object reusability.

## Introduction

Nowadays, Older adults or people with autism, or people with chronic illnesses need regular home healthcare or assistance with daily tasks for a specified period, hours, days, weeks, or other by a nurse or specialist.

In addition, the appropriate solution is to create an application that aims to assist a large population, such as the elderly, children, and people with disabilities, by requesting a nurse or specialized assistant to complete daily tasks for the user for hours or days.

The application is implemented using NetBeans and java programming language and graphical user interfaces. Also, the coding parts were implemented by using some design patterns such as singleton for the database object.

## **Business Scenario**

Initial assumption: the patient signs up for the system by entering his /her (first name, last name, phone number, SSN, Gender, Email, City, Age, Password, and choosing his or her type). Also, the medical employee can book an appointment.

Normal: The patient can book an appointment by choosing the type of medical employee he/she wants either nurse or a specialist.

## **Functional and non- Functional requirements**

### **Functional requirements**

#### **User requirements**

- Users can log in to the system if they do not have an account.
- Users can sign up for the system if they don't have an account.
- Patient can make his appointment upon his choices.
- Patients can choose the type of medical employees such as nurses and specialists and determine the appointment details.
- Patients can pay only by a credit card.
- The medical employees can add appointments.
- The medical employees and the patients can communicate with each other by an online chat.

## System Requirements

- Users can browse the system only if they have an account.
- Patient must have an account to pay for his order.
- Account linked with the customer's email.
- System offers online payment.
- The email shall be like the correct format for an email
- The users first name and the last name shall not be empty
- The system shall check if the email is in the database. If the email is not the database, the system shall not let the user use the system but if the email is in the system, then it will check the password.
- The phone number must be only digits and 10 digits only
- The card number length for the credit card shall be in 16 digits only
- The month and year and CCV of the credit card shall be digits
- The cardholder's name shall not be empty

## Non-functional requirements

- The system should be secure from any threats. The system shall protect the users information from any unauthorized access to the system.
- The system shall be available in 24 hours.
- The system is flexible and easy to use so that all types of customers can use the system without having any problems.
- The system should be able to maintain and update during the years.
- System should be capable of handling an infinite number of customers.

## Users view in iCare system

After collecting the requirements of the application, here is the system functionality and the actors down below:

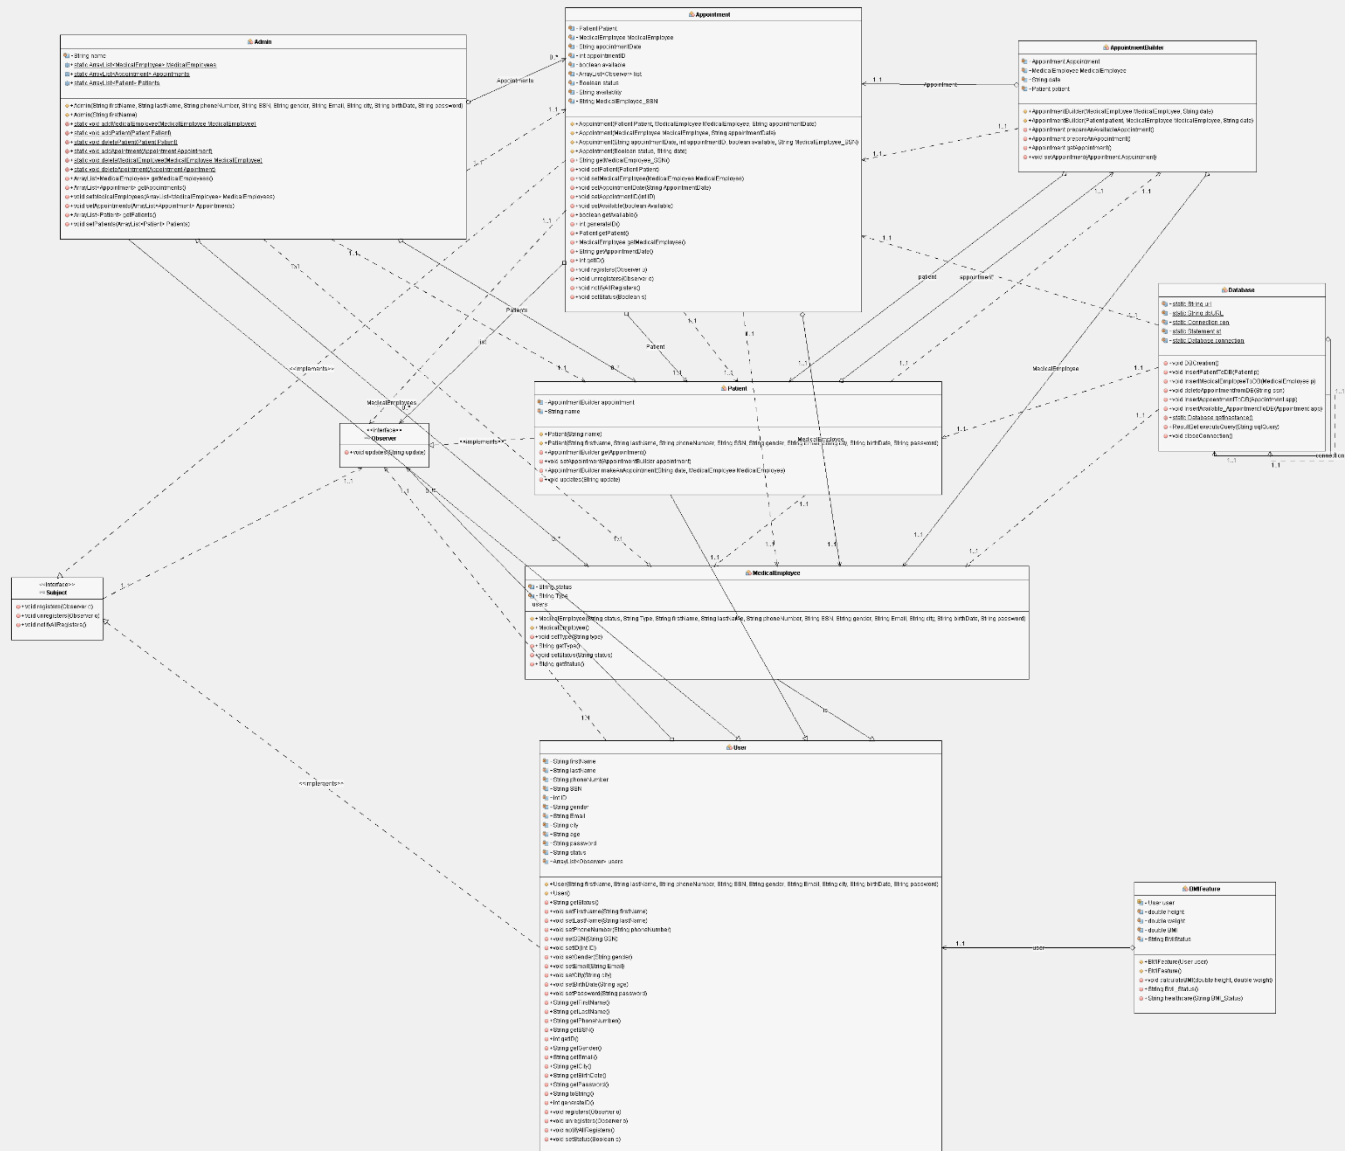

### Nurses and Specialists View

1. Add available appointments
2. Accept appointment requests
3. Direct contact with patients (Chatting)

### Patients View

1. Book appointments
2. Search for a specific assistant
3. Direct contact with assistants (Chatting)

## Dynamic class diagram of iCare application

## The implementation parts

In the iCare application, we used design patterns in the back end of the application. In fact, each design pattern is organized and made the coding easier and more reusable, and more efficient to work with. In fact, you can find below each definition of the design patterns that we used in the iCare application and the purpose of using it.

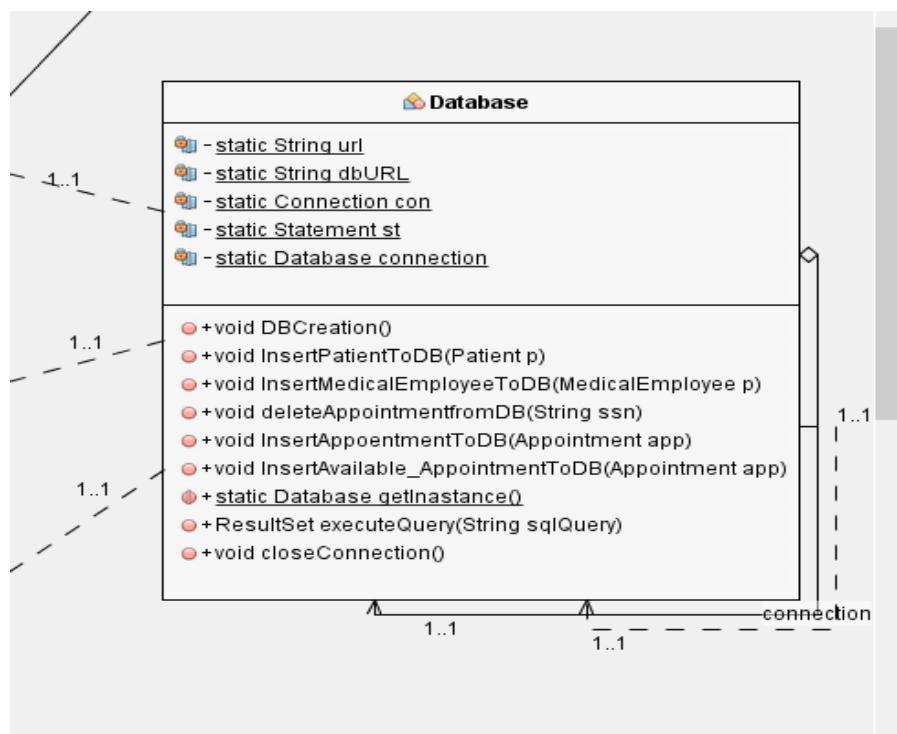

### Singleton design pattern

#### What is the singleton design pattern?

singleton design is one of the simplest design patterns. This type of design pattern comes under creational pattern as this pattern provides one of the best ways to create an object.

#### What is the specific purpose of the singleton in iCare application?

In the iCare application, we used the singleton design pattern in creating only an object for accessing the database. This helps to secure the accessing of the database.

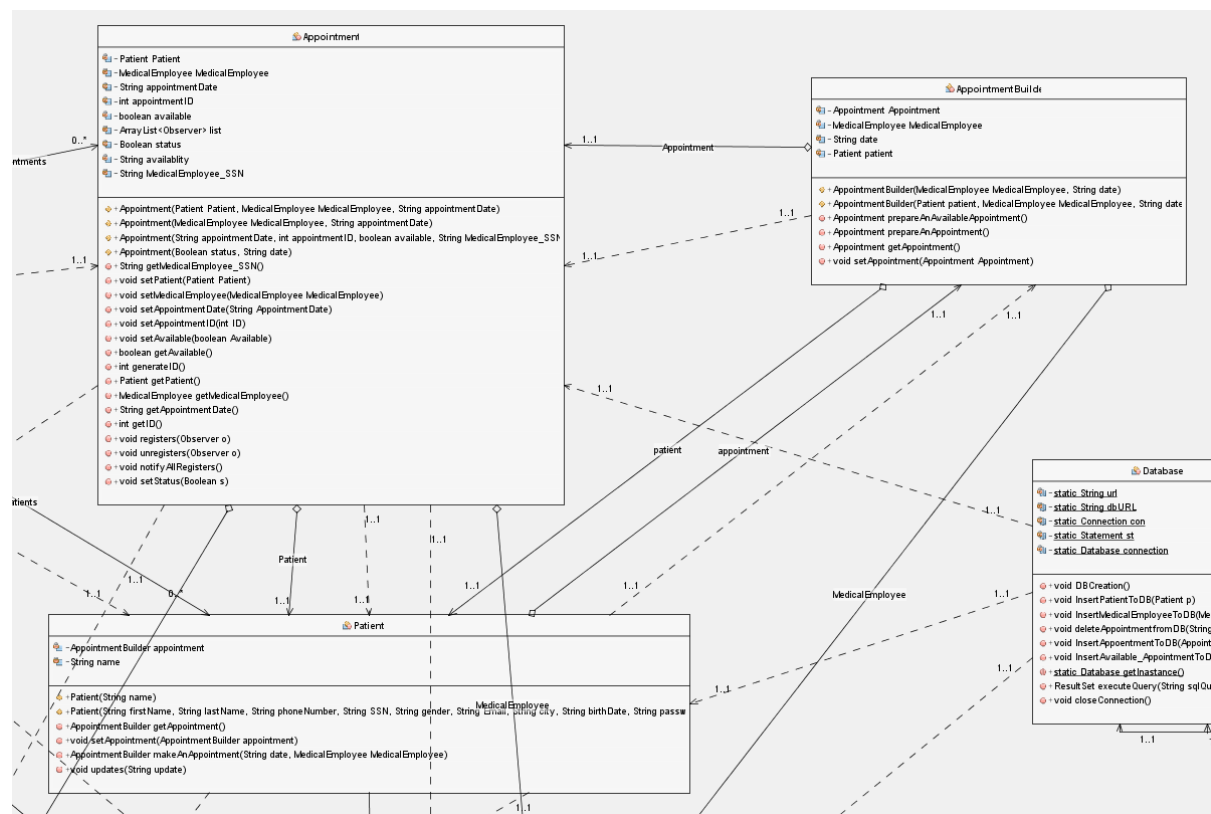

# Builder design pattern

## What is the builder creational design pattern?

The Builder Design Pattern is another creational pattern designed to deal with the construction of comparatively complex objects.

## What is the specific purpose of the Builder in iCare application?

In the iCare application, we used the builder to build an appointment. The patient is responsible to build his appointment with his specific criteria. In fact, the appointment has details which means that the patient should choose his appointment details based on his choices by a builder class.

## Decorator design pattern

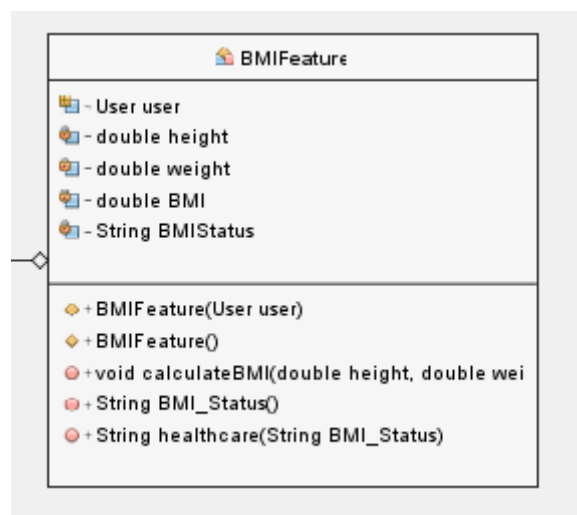

### What is the decorator design pattern?

A Decorator pattern can be used to attach additional responsibilities to an object either statically or dynamically. In addition, the decorator provides an enhanced interface to the original object.

### What is the specific purpose of the Decorator in iCare application?

Furthermore, there is an additional feature that was added in the iCare application and this feature works as a decorator of the application. Moreover, the feature is calculating body mass index which is an inexpensive and easy screening method for weight category (underweight, healthy weight, overweight, and obesity).

Also, BMI does not measure body fat directly, but BMI is moderately correlated with more direct measures of body fat.

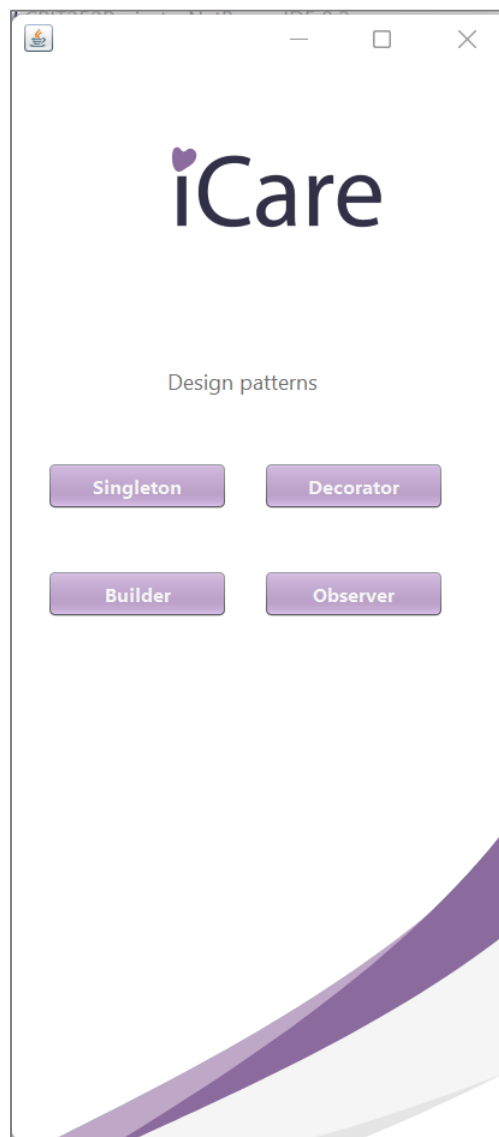

## Facade design pattern

What is the facade design pattern?

Facade encapsulates a complex subsystem behind a simple interface.

What is the specific purpose of the facade in iCare application?

It hides much of the complexity and makes the iCare easy to use.

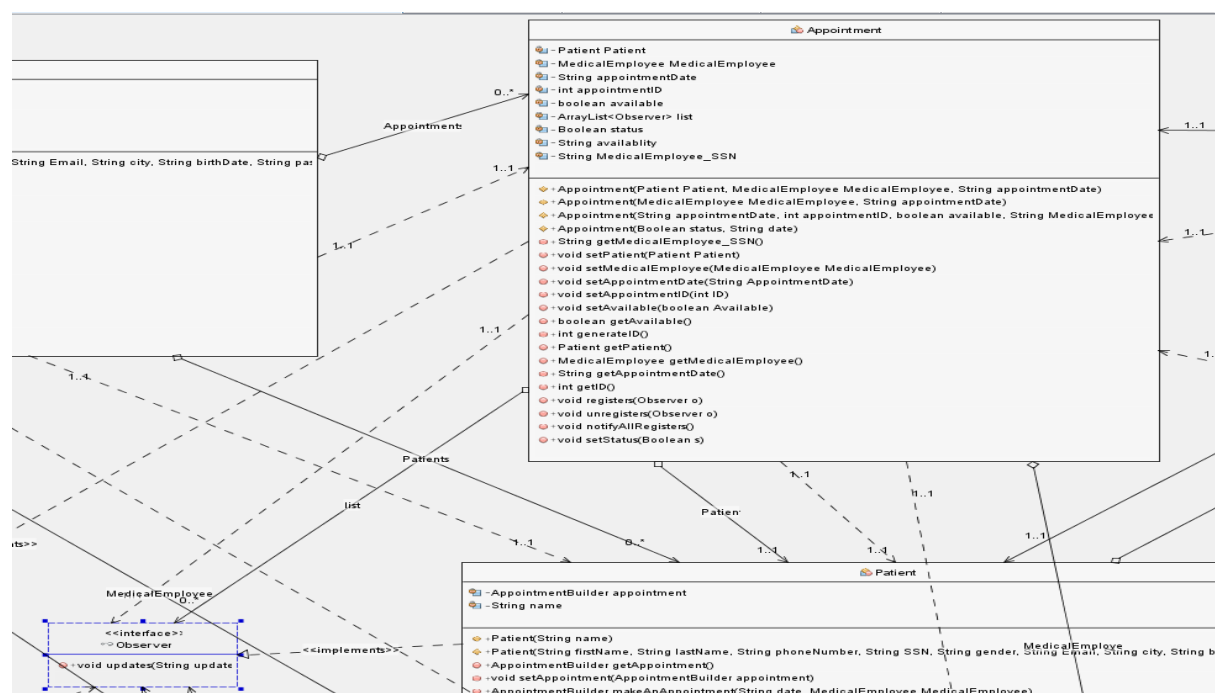

## Observer design pattern

## What is the observer design pattern?

Observer is a behavioural design pattern that defines a one-to-many dependency between objects so that when one object changes state, all its dependents are notified and updated automatically.

What is the specific purpose of the observer in iCare application?

iCare application can notify the patients about the changes in its states.

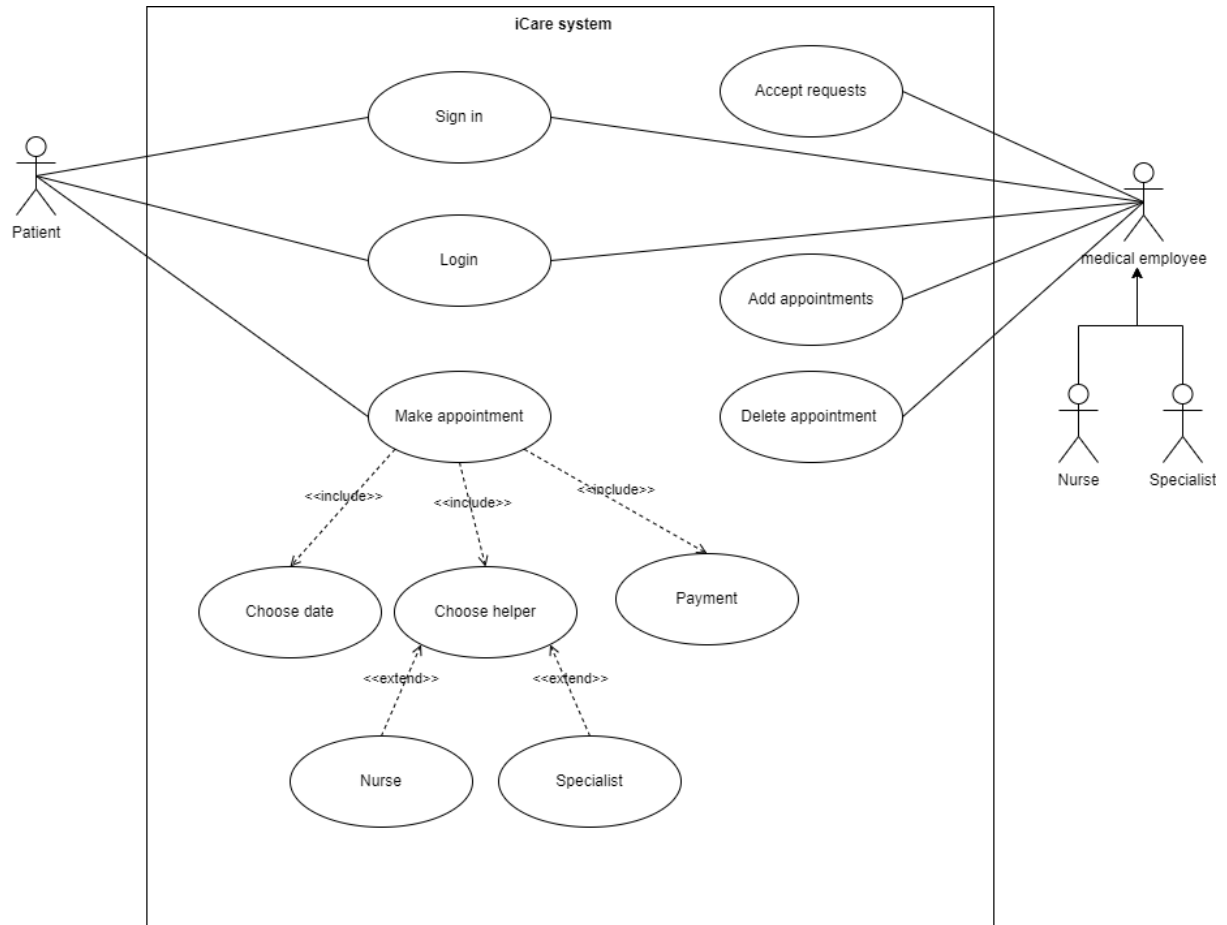

## Conclusion

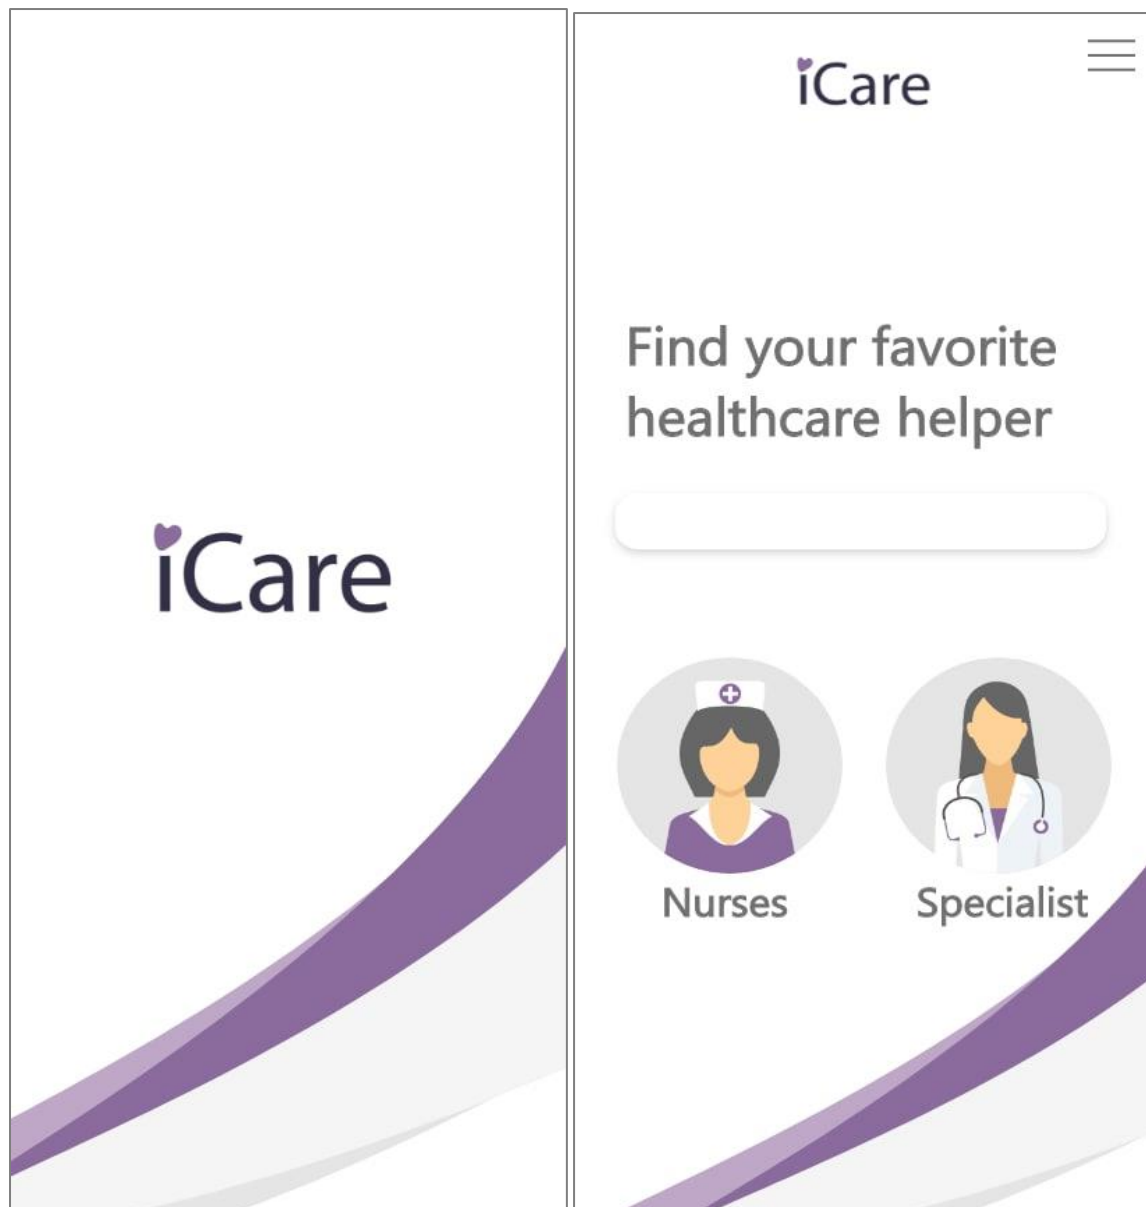

Finally, this report was written and designed to introduce our solution “iCare” to the problem of people who need frequent home healthcare or assistance with everyday duties from an expert for a certain length of time, hours, days, weeks, or months, which aims to provide an experience that saves user’s time and effort. We also seek in the future to add more ideas and develop this project by implementing the entire application instead of running only a few functions and adding new features.
